

 → [The JavaScript language](#) → [Objects: the basics](#)

Symbol type

By specification, object property keys may be either of string type, or of symbol type. Not numbers, not booleans, only strings or symbols, these two types.

Till now we've only seen strings. Now let's see the advantages that symbols can give us.

Symbols

"Symbol" value represents a unique identifier.

A value of this type can be created using `Symbol()` :

```
1 // id is a new symbol
2 let id = Symbol();
```

We can also give symbol a description (also called a symbol name), mostly useful for debugging purposes:

```
1 // id is a symbol with the description "id"
2 let id = Symbol("id");
```

Symbols are guaranteed to be unique. Even if we create many symbols with the same description, they are different values. The description is just a label that doesn't affect anything.

For instance, here are two symbols with the same description – they are not equal:

```
1 let id1 = Symbol("id");
2 let id2 = Symbol("id");
3
4 alert(id1 == id2); // false
```

If you are familiar with Ruby or another language that also has some sort of "symbols" – please don't be misguided. JavaScript symbols are different.

Symbols don't auto-convert to a string

Most values in JavaScript support implicit conversion to a string. For instance, we can `alert` almost any value, and it will work. Symbols are special. They don't auto-convert.

For instance, this `alert` will show an error:

```
1 let id = Symbol("id");
2 alert(id); // TypeError: Cannot convert a Symbol value to a string
```

If we really want to show a symbol, we need to call `.toString()` on it, like here:

```
1 let id = Symbol("id");
2 alert(id.toString()); // Symbol(id), now it works
```

That's a "language guard" against messing up, because strings and symbols are fundamentally different and should not occasionally convert one into another.

"Hidden" properties

Symbols allow us to create "hidden" properties of an object, that no other part of code can occasionally access or overwrite.

For instance, if we want to store an "identifier" for the object `user`, we can use a symbol as a key for it:

```

1 let user = { name: "John" };
2 let id = Symbol("id");
3
4 user[id] = "ID Value";
5 alert( user[id] ); // we can access the data using the symbol as the key

```

What's the benefit of using `Symbol("id")` over a string `"id"` ?

Let's make the example a bit deeper to see that.

Imagine that another script wants to have its own `"id"` property inside `user`, for its own purposes. That may be another JavaScript library, so the scripts are completely unaware of each other.

Then that script can create its own `Symbol("id")`, like this:

```

1 // ...
2 let id = Symbol("id");
3
4 user[id] = "Their id value";

```

There will be no conflict, because symbols are always different, even if they have the same name.

Now note that if we used a string `"id"` instead of a symbol for the same purpose, then there *would* be a conflict:

```

1 let user = { name: "John" };
2
3 // our script uses "id" property
4 user.id = "ID Value";
5
6 // ...if later another script the uses "id" for its purposes...
7
8 user.id = "Their id value"
9 // boom! overwritten! it did not mean to harm the colleague, but did it!

```

Symbols in a literal

If we want to use a symbol in an object literal, we need square brackets.

Like this:

```

1 let id = Symbol("id");
2
3 let user = {
4   name: "John",
5   [id]: 123 // not just "id: 123"
6 };

```

That's because we need the value from the variable `id` as the key, not the string `"id"`.

Symbols are skipped by for...in

Symbolic properties do not participate in `for...in` loop.

For instance:

```

1 let id = Symbol("id");
2 let user = {
3   name: "John",
4   age: 30,
5   [id]: 123
6 };
7
8 for (let key in user) alert(key); // name, age (no symbols)
9
10 // the direct access by the symbol works
11 alert( "Direct: " + user[id] );

```

That's a part of the general "hiding" concept. If another script or a library loops over our object, it won't unexpectedly access a symbolic property.

In contrast, `Object.assign` copies both string and symbol properties:

```

1 let id = Symbol("id");
2 let user = {
3   [id]: 123
4 };
5
6 let clone = Object.assign({}, user);
7
8 alert( clone[id] ); // 123

```

There's no paradox here. That's by design. The idea is that when we clone an object or merge objects, we usually want *all* properties to be copied (including symbols like `id`).

i Property keys of other types are coerced to strings

We can only use strings or symbols as keys in objects. Other types are converted to strings.

For instance, a number `0` becomes a string `"0"` when used as a property key:

```

1 let obj = {
2   0: "test" // same as "0": "test"
3 };
4
5 // both alerts access the same property (the number 0 is converted to string "0")
6 alert( obj["0"] ); // test
7 alert( obj[0] ); // test (same property)

```

Global symbols

As we've seen, usually all symbols are different, even if they have the same names. But sometimes we want same-named symbols to be same entities.

For instance, different parts of our application want to access symbol `"id"` meaning exactly the same property.

To achieve that, there exists a *global symbol registry*. We can create symbols in it and access them later, and it guarantees that repeated accesses by the same name return exactly the same symbol.

In order to create or read a symbol in the registry, use `Symbol.for(key)`.

That call checks the global registry, and if there's a symbol described as `key`, then returns it, otherwise creates a new symbol `Symbol(key)` and stores it in the registry by the given `key`.

For instance:

```

1 // read from the global registry
2 let id = Symbol.for("id"); // if the symbol did not exist, it is created
3
4 // read it again
5 let idAgain = Symbol.for("id");
6
7 // the same symbol
8 alert( id === idAgain ); // true

```

Symbols inside the registry are called *global symbols*. If we want an application-wide symbol, accessible everywhere in the code – that's what they are for.

i That sounds like Ruby

In some programming languages, like Ruby, there's a single symbol per name.

In JavaScript, as we can see, that's right for global symbols.

Symbol.keyFor

For global symbols, not only `Symbol.for(key)` returns a symbol by name, but there's a reverse call: `Symbol.keyFor(sym)`, that does the reverse: returns a name by a global symbol.

For instance:

```

1 let sym = Symbol.for("name");
2 let sym2 = Symbol.for("id");
3
4 // get name from symbol

```

```
5 alert( Symbol.keyFor(sym) ); // name
6 alert( Symbol.keyFor(sym2) ); // id
```

The `Symbol.keyFor` internally uses the global symbol registry to look up the key for the symbol. So it doesn't work for non-global symbols. If the symbol is not global, it won't be able to find it and return `undefined`.

For instance:

```
1 alert( Symbol.keyFor(Symbol.for("name")) ); // name, global symbol
2
3 alert( Symbol.keyFor(Symbol("name2")) ); // undefined, the argument isn't a global symbol
```

System symbols

There exist many "system" symbols that JavaScript uses internally, and we can use them to fine-tune various aspects of our objects.

They are listed in the specification in the [Well-known symbols](#) table:

- `Symbol.hasInstance`
- `Symbol.isConcatSpreadable`
- `Symbol.iterator`
- `Symbol.toPrimitive`
- ...and so on.

For instance, `Symbol.toPrimitive` allows us to describe object to primitive conversion. We'll see its use very soon.

Other symbols will also become familiar when we study the corresponding language features.

Summary

`Symbol` is a primitive type for unique identifiers.

Symbols are created with `Symbol()` call with an optional description.

Symbols are always different values, even if they have the same name. If we want same-named symbols to be equal, then we should use the global registry: `Symbol.for(key)` returns (creates if needed) a global symbol with `key` as the name. Multiple calls of `Symbol.for` return exactly the same symbol.

Symbols have two main use cases:

1. "Hidden" object properties. If we want to add a property into an object that "belongs" to another script or a library, we can create a symbol and use it as a property key. A symbolic property does not appear in `for...in`, so it won't be occasionally listed. Also it won't be accessed directly, because another script does not have our symbol, so it will not occasionally intervene into its actions.

So we can "covertly" hide something into objects that we need, but others should not see, using symbolic properties.

2. There are many system symbols used by JavaScript which are accessible as `Symbol.*`. We can use them to alter some built-in behaviors. For instance, later in the tutorial we'll use `Symbol.iterator` for [iterables](#), `Symbol.toPrimitive` to setup [object-to-primitive conversion](#) and so on.

Technically, symbols are not 100% hidden. There is a built-in method `Object.getOwnPropertySymbols(obj)` that allows us to get all symbols. Also there is a method named `Reflect.ownKeys(obj)` that returns *all* keys of an object including symbolic ones. So they are not really hidden. But most libraries, built-in methods and syntax constructs adhere to a common agreement that they are. And the one who explicitly calls the aforementioned methods probably understands well what he's doing.
